Statement of need

Surface area determination is important for the evaluation of a porous material's viability in applications ranging from catalysis to separations to gas storage. The most widely used approach for the evaluation of a material's specific surface area, i.e. surface area per unit mass, is Brunauer-Emmett-Teller (BET) theory (Brunauer et al., 1938). Given the adsorption isotherm of a gas in an adsorbent, one can use BET theory to determine the specific surface area of the adsorbent upon identification of an appropriate linear region in the isotherm. This procedure is sometimes automatically performed by the software program that comes with the commercial adsorption apparatus that measures the adsorption isotherm. Unfortunately, the linear region selection is a large source of variability in BET-calculated areas. In addition, for certain types of isotherms, automatic selection of the linear region by the commercial software sometimes fails. As a result, many researchers perform the analyses manually on a spreadsheet, which can become time-consuming and nearly impossible for some types of isotherms (Osterrieth et al., 2022). These challenges have motivated the development of programs for the automated determination of BET areas (Datar et al., 2020; Iacomi & Llewellyn, 2019; Osterrieth et al., 2022; Sadeghi et al., 2020; Sinha et al., 2019). Furthermore, shortcomings of BET as a tool for surface area calculation, such as its relatively poor performance in treating high surface area materials with multimodal pore sizes (Gómez-Gualdrón et al., 2016; Wang et al., 2015), have led to the development of alternate methods for surface area calculation from isotherms (Datar et al., 2020; Sinha et al., 2019).

Summary

In contrast to previously developed programs which require use of the command line (Iacomi & Llewellyn, 2019; Osterrieth et al., 2022) and familiarity with Python (Datar et al., 2020; Iacomi & Llewellyn, 2019; Sinha et al., 2019), the SESAMI web interface allows a user to generate surface area predictions on their web browser by uploading isotherm data. The website facilitates access to the previously developed SESAMI models (SESAMI 1 and 2) for porous material surface area prediction (Datar et al., 2020; Sinha et al., 2019) and has been tested by experimental groups. The motivation for this interface is to lower the barrier of entry for research groups seeking to use SESAMI code, which was previously packaged in Python and Jupyter Notebook scripts.

SESAMI 1 applies computational routines to identify suitable linear regions of adsorption

isotherms for Brunauer-Emmett-Teller surface area prediction (Fagerlund, 1973). The automated workflow includes consideration of Rouquerol criteria (J. Rouquerol et al., 2007; Jean Rouquerol et al., 2013) and the use of coefficients of determination as a measure of linearity. Furthermore, SESAMI 1 supports a combined BET+ESW (excess sorption work) approach for linear region selection; this combined approach has been shown to outperform the BET approach in some cases (Sinha et al., 2019). A user can specify a cutoff R^2 and a minimum R^2, such that a candidate linear region is favored to be selected if it has an R^2 above the cutoff, and a candidate linear region is only considered if it has an R^2 above the minimum. On the other hand, SESAMI 2 applies a machine learning (specifically, regularized linear regression with LASSO) model for the accurate surface area prediction of high surface area materials, improving on BET performance for these materials (Datar et al., 2020). The LASSO model uses as input the average loading in seven isotherm pressure regions as well as pairwise products of these loadings. The SESAMI routines support isotherms with N_2 and argon adsorbate at 77 K or 87 K, respectively.

The SESAMI web interface has extensive error handling and clearly alerts users of issues with their adsorption isotherm data. For example, it alerts the user if no ESW minima is found by SESAMI 1 or if the data is incompatible with SESAMI 2 code due to data sparsity in certain pressure regions. As shown in Figure 1, the interface displays SESAMI 1 calculation results including information on the chosen linear region, namely the satisfied Rouquerol criteria (J. Rouquerol et al., 2007; Jean Rouquerol et al., 2013), the pressure range and number of data points in the region, and the coefficient of determination. The interface also displays intermediate SESAMI 1 values for surface area calculation, namely the BET constant, C, and the monolayer adsorption loading, q_m. Furthermore, the SESAMI web interface allows the user to download figures generated by SESAMI 1 that indicate, among other things, the chosen linear monolayer loading regions by the BET and BET+ESW approaches as well as the excess sorption work plot (Figure 1). The user can convert output from commercial equipment to AIF format and upload the converted data to the interface for analysis. The SESAMI web interface is publicly available at https://sesami-web.org/, and source code is available at https://github.com/hjkgrp/SESAMI_web.

a)

SESAMI 1.0 (BET) results are:

BET area = 2430.9 m^2/g
C = 201.1
q_m = 28.42 mol/kg
Rouquerol consistency criteria 1 and 2: Yes
Rouquerol consistency criterion 3: Yes
Rouquerol consistency criterion 4: Yes
Number of points in linear region: 9
Lowest pressure of linear region: 3500 Pa
Highest pressure of linear region: 8000 Pa
R^2 of linear region: 0.9996

SESAMI 1.0 (BET+ESW) results are:

BET area = 2346.7 m^2/g
C = 248.1
q_m = 27.44 mol/kg
Rouquerol consistency criteria 1 and 2: Yes
Rouquerol consistency criterion 3: No
Rouquerol consistency criterion 4: Yes
Number of points in linear region: 9
Lowest pressure of linear region: 600 Pa
Highest pressure of linear region: 1500 Pa
R^2 of linear region: 0.9985

SESAMI 2.0 (LASSO) surface area prediction is:

2099.1 m^2/g

Benchmarking

To assess the performance of SESAMI code in predicting surface areas from isotherms, we benchmarked the SESAMI routines against other similar programs for 13 simulated and 9 experimental N_2 isotherms obtained at 77 K for 14 metal-organic frameworks, some of which are shown in Figure 2. Simulated isotherms were obtained from Grand Canonical Monte Carlo (GCMC) simulations using RASPA open-source software (Dubbeldam et al., 2016), and experimental adsorption isotherms were obtained from the experimental data reported

by Islamogu and coworkers (Islamoglu et al., 2022). The data were then used to calculate the surface areas from the SESAMI website, BETSI (Osterrieth et al., 2022; Rampersad et al., 2020), pyGAPS (Iacomi, 2019; Iacomi & Llewellyn, 2019), and BEaTmap (Sadeghi et al., 2020).

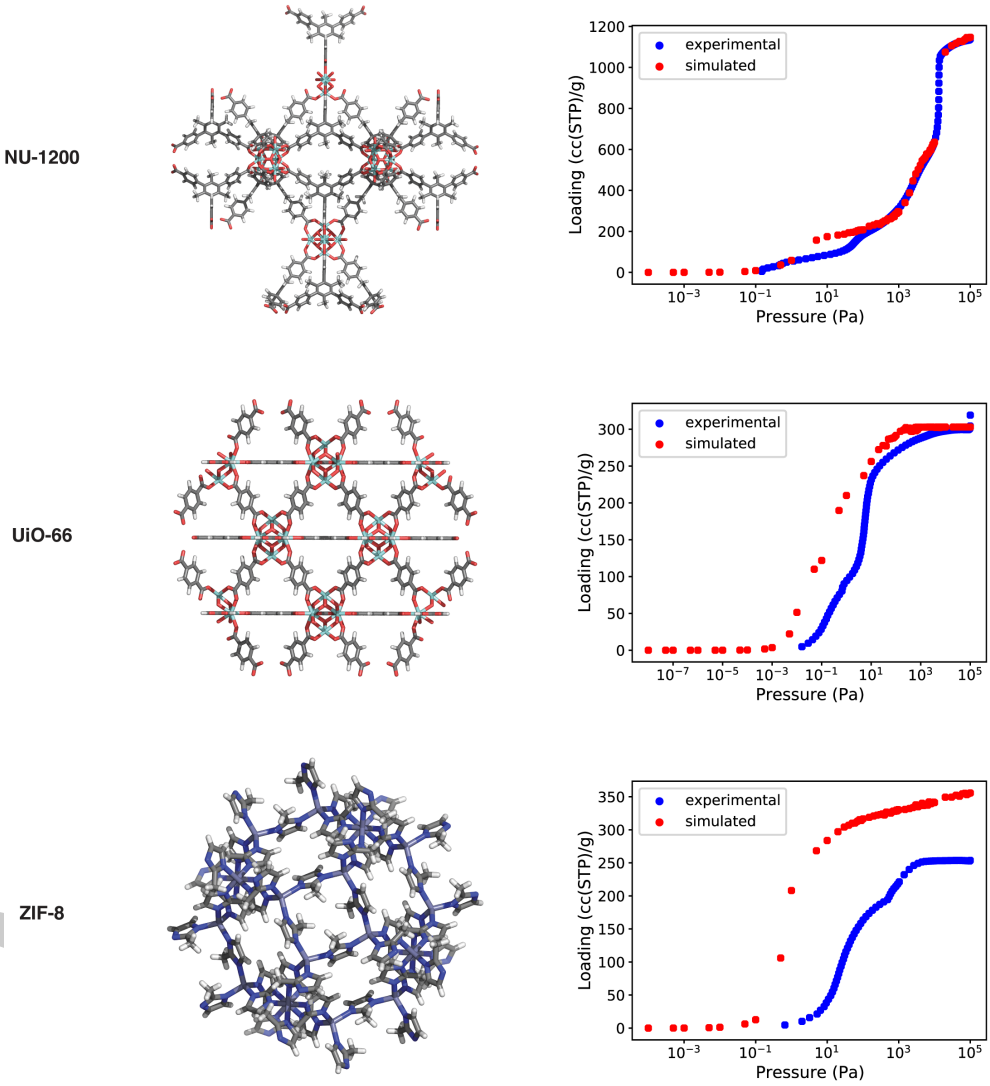

Figure 2: The crystal structures and isotherms of 3 of the 14 metal-organic frameworks used to benchmark different isotherm to surface area codes.

We find that over the set of 13 GCMC isotherms, the SESAMI machine learning model and BEaTmap have the best correlation with Zeo++ surface areas (Willems et al., 2012) calculated with a 1.67 Å probe N_2 molecule (Tables 2 and 1). Nevertheless, all software are in generally good agreement, underscoring the benefit of a computational approach to surface area calculation. The agreement between software is also not surprising due to the similar approach taken by most of the codes of considering multiple subsets of consecutive data points and applying checks like the Rouquerol criteria to select a linear region for BET analysis. Indeed, this agreement is also observed over the 9 experimental isotherms (Table 3). The benchmark isotherms, XLSX files of surface area predictions across different software tools for both GCMC and experimental isotherms, details about settings used for each software, and employed analysis scripts are available at https://github.com/hjkgrp/SESAMI_web.

Table 1: Calculated surface areas (m^2/g) for the 13 MOFs with GCMC isotherms. Cases where a software does not find a surface area are denoted by N/A. Zeo++ calculations were conducted with the same CIF files used to generate GCMC isotherms, and a 1.67 Å probe N_2 molecule, the high accuracy flag, and 2,000 samples were used. All other software took as input the GCMC isotherms.
